8. Appendix 19

1. Introduction

This package is essentially a replacement—partial or total—for the \LaTeX\ macros related with sections—namely titles, headers and contents. The goal is to provide new features unavailable in current \LaTeX; if you just want a more friendly interface than that of standard \LaTeX but without changing the way \LaTeX works you may consider using fancyhdr, by Piet van Oostrum, sectsty, by Rowland McDonnell, and toloft, by Peter Wilson, which you can make pretty things with.¹

Some of the new features provided are:

- Different classes and “shapes” of titles, with tools for very fancy formats. You can define different formats for left and right pages, or numbered and unnumbered titles, measure the width of the title, add a new section level, use graphics, and many more. The Appendix shows a good deal of examples, so jump forward right now!

- Headers and footers defined with no \ldots mark intermediates, and perhaps containing top, first and bot marks at the same time. Top marks correctly synchronized with titles, without incompatibilities with the float mechanism. Decorative elements easily added, including picture environments.

¹The titlesec package is currently at version 2.10.2. © 1998–2016 Javier Bezos. The titletoc package is currently at version 1.6. The titleps package is currently at version 1.1.1 © 1999–2016 Javier Bezos. All Rights Reserved.

†For bug reports, comments and suggestions go to http://www.tex-tipografia.com/contact.html English is not my strong point, so contact me when you find mistakes in the manual. Other packages by the same author: gloss (with José Luis Díaz), enumitem, accents, tensind, esindex, dotlessi, babeltools.

1Since the sectioning commands are rewritten, their behaviour could be somewhat different in some cases.
- Pretty free form contents, with the possibility of grouping entries of different levels in a paragraph or changing the format of entries in the middle of a document.

Titlesec works with the standard classes and with many others, including the AMS ones, and it runs smoothly with hyperref. Unfortunately, it is not compatible with memoir, which provides its own tools with a limited subset of the features available in titlesec.

As usual, load the package in the standard way with \usepackage. Then, redefine the sectioning commands with the simple, predefined settings (see section “Quick Reference”) or with the provided commands if you want more elaborate formats (see section “Advanced Interface.”) In the latter case, you only need to redefine the commands you’ll use. Both methods are available at the same time, but because \part is usually implemented in a non-standard way, it remains untouched by the simple settings and should be changed with the help of the “Advanced Interface.”

2. Quick Reference

The easiest way to change the format is by means of a set of package options and a couple of commands. If you feel happy with the functionality provided by this set of tools, you need not go further in this manual. Just read this section and ignore the subsequent ones.

2.1. Format

There are three option groups controlling font, size and align. You need not set all of these groups, since a default is provided for each one; however, you must use at least an option from them if you want this “easy setup.”

\texttt{rm sf tt md bf up it sl sc}

Select the corresponding family/series/shape. Default is \texttt{bf}.

\texttt{big medium small tiny}

Set the size of titles. Default is \texttt{big}, which gives the size of standard classes. With \texttt{tiny}, sections (except chapters) are typed in the text size. \texttt{medium} and \texttt{small} are intermediate layouts.

\texttt{raggedleft center raggedright}

Control the alignment.

2.2. Spacing

\texttt{compact}

This option is independent from those above and reduces the spacing above and below the titles.

2.3. Uppercase

\texttt{uppercase}

\texttt{2.9} Uppercases titles. Depending on the class, it might not work in \texttt{chapter} and \texttt{part}.

2.4. Tools

\texttt{\titlelabel{⟨label-format⟩}}

Changes the label format in sections, subsections, etc. A \texttt{\thetitle} command is provided which is respectively \texttt{\thesection}, \texttt{\thesubsection}, etc. The default value in standard classes is

\texttt{\part}

However, be aware the AMS classes reimplement the original internal commands. These changes will be lost here. The compatibility with \texttt{hyperref} has been tested with \texttt{dvips}, \texttt{dvipdfm} and \texttt{pdftex} but it is an unsupported feature. Please, check your version of \texttt{hyperref} is compatible with \texttt{titlesec}.
\titlelabel{\thetitle\quad}
and you may add a dot after the counter simply with
\titlelabel{\thetitle.\quad}
That was done in this document.

\titleformat*{⟨command⟩}{⟨format⟩}
This command allows to change the ⟨format⟩ of a sectioning command, as for example:
\titleformat*{\section}{\itshape}

3. Advanced Interface
Two commands are provided to change the title format. The first one is used for the “internal” format, i. e., shape, font, label. . . , the second one defines the “external” format, i. e., spacing before and after, indentation, etc. This scheme is intended to easy definitions, since in most of cases you will want to modify either spacing or format. That redefines existing sectioning commands, but does not create new ones. New sectioning levels can be added with \titleclass, as described below, and then their format can be set with the commands described here.

3.1. Format
A set of shapes is provided, which controls the basic distribution of elements in a title. The available shapes are:

hang is the default value, with a hanging label. (Like the standard \section.)

block typesets the whole title in a block (a paragraph) without additional formatting. Useful in centered titles and special formatting (including graphic tools such as picture, pspicture, etc.)

display puts the label in a separate paragraph. (Like the standard \chapter.)

runin A run-in title, like the standard \paragraph.

leftmargin puts the title at the left margin. Titles at the very end of a page will be moved to the next one and will not stick out in the bottom margin, which means large titles can lead to underfull pages. In this case you may increase the stretchability of the page elements, use \raggedbottom or use the package option nobottomtitles described below. Since the mechanism used is independent from that of the margin pars, they can overlap. A deprecated synonymous is margin.

rightmargin is like leftmargin but at the right margin.

drop wraps the text around the title, provided the first paragraph is longer than the title (if not, they overlap). The comments in leftmargin also apply here.

wrap is quite similar to drop. The only difference is while the space reserved in drop for the title is fixed, wrap is automatically readjusted to the longest line. The limitations explained below related to calcwidth also apply here.

3Information is “extracted” from the class sectioning commands, except for chapter and part. Standard definitions with \@startsection are presumed—if sections have been defined without that macro, arbitrary values for the format an the spacing are provided, which you may change later. (Sadly, there is no way to catch the chapter or part formats, and one similar to that of standard classes will be used.)

4The label will be slightly displaced to the left if the title is two or more lines long and the hang shape is used, except with explicit \.

5Well, not quite. The title is first boxed to avoid some unexpected results if, for example, there is a \color between the title and the text. Unfortunately, due to an optimization done by \LaTeX{} discretionaries may be lost. I have found no solution, except using \ latex, which works as one could expect. Anyway, if the title doesn’t contain hyphen or dashes, this is not usually a real problem.

6However, floats following the title a couple of lines after will interfere with the page breaking used here and sometimes the title may stick out.
frame  Similar to display, but the title will be framed.

Note, however, some shapes do not make sense in chapters and parts.

\titleformat{(command)}{(shape)}{(format)}{(label)}{(sep)}{(before-code)}{(after-code)}

Here

- (command) is the sectioning command to be redefined, i.e., \part, \chapter, \section, \subsection, \subsubsection, \paragraph or \subparagraph.
- The paragraph shape is set by (shape), whose possible values are those described above.
- (format) is the format to be applied to the whole title—label and text. This part can contain vertical material (and horizontal with some shapes) which is typeset just after the space above the title.
- The label is defined in (label). You may leave it empty if there is no section label at that level, but this is not recommended because by doing so the number is not suppressed in the table of contents and running heads.
- (sep) is the horizontal separation between label and title body and must be a length (it must not be empty). This space is vertical in display shape; in frame it is the distance from text to frame. Both (label) and (sep) are ignored in starred versions of sectioning commands. If you are using picture and the like, set this parameter to 0 pt.
- (before-code) is code preceding the title body. The very last command can take an argument, which is the title text. However, with the package option explicit the title must be given explicitly with #1 (see below).
- (after-code) is code following the title body. The typeset material is in vertical mode with hang, block and display; in horizontal mode with runin and leftmargin (2.7 with the latter, at the beginning of the paragraph). Otherwise is ignored.

\chaptertitlename

It defaults to \chaptername except in appendices where it is \appendixname. Use it instead of \chaptername when defining a chapter.

3.2. Spacing

\titlespacing*(command){(left)}{(before-sep)}{(after-sep)}{(right-sep)}

The starred version kills the indentation of the paragraph following the title, except in drop, wrap and runin where this possibility does not make sense.

- (left) increases the left margin, except in the \...margin, and drop shape, where this parameter sets the title width, in wrap, the maximum width, and in runin, the indentation just before the title. With negative value the title overhangs.
- (before-sep) is the vertical space before the title.
- (after-sep) is the separation between title and text—vertical with hang, block, and display, and horizontal with runin, drop, wrap and \...margin. By making the value negative, you may define an effective space of less than \parskip.

\footnote{Remember font size can be changed safely between paragraphs only, and changes in the text should be made local with a group; otherwise the leading might be wrong—too large or too small.}

\footnote{This parameter is not equal to <indent> of \@startsection, which doesn’t work correctly. With a negative value in the latter and if <indent> is larger than the label width, the first line of the title will start in the outer margin, as expected, but the subsequent lines will not; worse, those lines will be shortened at the right margin.}

\footnote{See Goossens, Mittelbach and Samarin: \textit{The \LaTeX Companion}, Reading, Addison Wesley, 1993, p. 25.}
• The hang, block and display shapes have the possibility of increasing the (right-sep) margin with this optional argument.

If you dislike typing the full skip values, including the plus and minus parameters, an abbreviation *n is provided. In the (before-sep) argument this is equivalent to n \text{ex} with some stretchability and a minute shrinkability. In the (after-sep) some stretchability (smaller) and no shrinkability Thus, you can write

\titlespacing{\section}{0pt}{*4}{*1.5}

The lengths \beforetitleunit and \aftertitleunit are used as units in the * settings and you can change them if you do not like the predefined values (or for slight changes in the makeup, for example).

Notes. \titlespacing does not work with either \chapter and \part unless you change its title format as well by means of \titleformat, the simple settings, or \titleclass. Arguments in \titlespacing must be dimensions; \stretch includes a command and hence raises an error.

3.3. Spacing related tools

These commands are provided as tools for \titleformat and \titlespacing.

\filright \filcenter \filleft \fillast \fillinner \filouter

Variants of the \ragged... commands, with slight differences. In particular, the \ragged... commands kills the left and right spaces set by \titlespacing\fillast justifies the paragraph, except the last line which is centered These commands work in the frame label, too. \fillinner and \filouter are \filleft or \filright depending on the page. Because of the asynchronous \TeX page breaking, these commands can be used in \chapter only. If you want a general tool to set different formats depending on the page, see “Extended settings” below.

\wordsep

The inter-word space for the current font.

indentafter noindentafter (Package options)

By-pass the settings for all of sectioning commands

rigidchapters rubberchapters (Package options)

With rigidchapters the space for chapter titles is always the same, and \after-sep in \titlespacing does not mean the space from the bottom of the text title to the text body as described above, but from the top of the text title, i.e., \before-sep + \after-sep now is a fixed distance from the top of the page body to the main text. The default is rubberchapters where \after-sep is the separation between title and text as usual. Actually, the name is misleading because it applies not only to the default chapter, but to any title of top class. (More on classes below.)

bottomtitles nobottomtitles nobottomtitles* (Package options)

If nobottomtitles is set, titles close to the bottom margin will be moved to the next page and the margin will be ragged. The minimal space required in the bottom margin not to move the title is set (approximately) by

\renewcommand{\bottomtitlespace}{\langle length\rangle}
whose default value is 0.2\textheight. A simple ragged bottom on the page before is obtained with a value of 0 pt. \texttt{bottomtitles} is the default, which simply sets \texttt{\bottomtitlespace} to a negative value. The \texttt{nobottomtitles*} option provides more accurate computations but titles of margin, wrap or drop shapes could be badly placed. Usually, you should use the starred version.

\begin{center}
\texttt{aftersep largestsep} \textit{(Package options)}
\end{center}

By default, when there are two consecutive titles the \texttt{(after-sep)} space from the first one is used between them. Sometimes this is not the desired behaviour, especially when the \texttt{(before-sep)} space is much larger than the \texttt{(after-sep)} one (otherwise the default seems preferable). With \texttt{largestsep} the largest of them is used. Default is \texttt{aftersep}.

\begin{center}
\texttt{pageatnewline} \textit{(Package option)}
\end{center}

\textit{2.6} In version 2.6 and later, \texttt{\\} does not allow a page break and therefore is equivalent to \texttt{\\*}. Since I presume none wants a page break inside a title, this has been made the default. If for some extrange reason you want to allow page breaks inside the titles, use the package option \texttt{pageatnewline}, which is provided for backward compatibility.

\section*{3.4. Rules}

The package includes some tools for helping in adding rules and other stuff below or above the title. Since the margins in titles may be modified, these macros take into account the local settings to place rules properly. They also take into account the space used by marginal titles.

\begin{center}
\texttt{\\texttt{\titleline\[\langle align\rangle\]\{(horizontal material)\}}}
\texttt{\titlerule\[\langle height\rangle\]}
\texttt{\titlerule*\[\langle width\rangle\]\{(text)\}}
\end{center}

The \texttt{\titleline} command allows inserting a line, which may contain text and other “horizontal” material. it is intended mainly for rules and leaders but in fact is also useful for other purposes. The line has a fixed width and hence must be filled, i.e., \texttt{\titleline\{CHAPTER\}} produces an underfull box. Here the optional \texttt{(align)} \texttt{(l, r or c)} helps, so that you simply type, say, \texttt{\titleline[c]\{CHAPTER\}}.

Using \texttt{\titleline} in places where vertical material is not expected can lead to anomalous results. In other words, you can use it in the \texttt{(format)} (always) and \texttt{(after-code)} (hang, display and block) arguments; and in the display shape at the very beginning of the \texttt{(before-code)} and \texttt{(label)} argument as well. But try it out, because very likely it works in other places.

The \texttt{\titlerule} command, which is enclosed automatically in \texttt{\titleline} if necessary, can be used to build rules and fillers. The unstarred version draws rules of height 4 pt, or \texttt{(height)} if present. For example:

\begin{verbatim}
\titlerule[.8pt]$
\vspace{1pt}$
\titlerule
draws two rules of different heights with a separation of 1 pt.
\end{verbatim}

The starred version makes leaders with the \texttt{(text)} repeated in boxes of its natural width. The width of the boxes can be changed to \texttt{(width)}, but the first box remains with its natural width so that the \texttt{(text)} is aligned to the left and right edges of the space to be filled.

For instance, with

\begin{verbatim}
\titleformat{\section}[leftmargin]
{\titlerule*[1pc][]$
\vspace{1ex}$
\bfseries}
{... definition follows}
\end{verbatim}

\footnote{The default is the \texttt{s} parameter of the \texttt{\makebox} command.}
leaders spanning over both main text and title precede the section.

**calcwidth** (Package option)

The wrap shape has the capability of measuring the lines in the title to format the paragraph. This capability may be extended to other three shapes—namely display, block and hang—with this package option. The length of the longest line is returned in $\textwidth$.

As far as \TeX{} is concerned, any box is considered typeset material. If the box has been enlarged with blank space, or if conversely a box with text has been smashed, the value of $\textwidth$ may be wrong (as far as humans is concerned). The hang shape, for instance, uses internally such a kind of boxes, but in this case this behaviour is desired when the title is flushed right; otherwise the block shape produces better results. In other words, using boxes whose natural width has been overridden may be wrong. Further, some commands may confuse \TeX{} and stop parsing the title. But if you stick to text, `\` and `\[...]` (and it is very unlikely you might want something else), there will be no problems.

Another important point is the ⟨before-code⟩, ⟨label⟩, ⟨sep⟩, and ⟨title⟩ parameters (but not ⟨after-code⟩) are evaluated twice at local scope; if you increase a counter globally, you are increasing it twice. In most of cases, placing the conflicting assignment in the ⟨after-code⟩ parameter will be ok, but alternativey you can use the following macro.

\iftitlemeasuring{⟨true⟩}{⟨false⟩}

When the title is being measured (first pass), the ⟨true⟩ branch is used, and when the title is actually typeset (second pass) the ⟨false⟩ branch is used.

\titleline*[⟨align⟩]{⟨horizontal material⟩}

A variant of \titleline to be used only with \calcwidth. The text will be enclosed first in a box of width $\textwidth$; this box will be in turn enclosed in the main box with the specified alignment. There is no equivalent \titlerule and therefore you must enclose it explicitly in a \titleline* if you want the $\textwidth$ to be taken into account:

\titleline*[c]{\titlerule[.8pc]}

### 3.5. Page styles

2.8 You can assign a page style to levels of class top and page, as well as the default chapter with the following command:

\assignpagestyle{⟨command⟩}{⟨pagestyle⟩}

For example, to suppress the page number in chapters write:

\assignpagestyle{\chapter}{empty}

### 3.6. Breaks

<table>
<thead>
<tr>
<th>\sectionbreak</th>
<th>\subsectionbreak</th>
<th>\subsubsectionbreak</th>
</tr>
</thead>
<tbody>
<tr>
<td>\paragraphbreak</td>
<td>\subparagraphbreak</td>
<td>\langle section⟩break</td>
</tr>
</tbody>
</table>

By defining these command with \newcommand different page breaks could be applied to different levels. In those undefined, a penalty with the internal value provided by the class is used (typically −300). For instance,

\footnote{15There are two further parameters, \textwidthfirst and \textwidthlast, which return the length of the first and last lines. There are not specific tools for using them, but you can assign their values to \textwidth and then use \titleline*.}

\footnote{16Which include justified lines, whose interword spacing has been enlarged.}

\footnote{17Named in the short-lived version 2.7 as \titlepagestyle.}
\newcommand{\sectionbreak}{\clearpage}

makes sections begin a new page. In some layouts, the space above the title is preserved even if the
section begins a new page; that’s accomplished with:

\newcommand{\sectionbreak}{%
  \addpenalty{-300}%
  \vspace*{0pt}}%

2.6 \sectionbreak is available in the top class, too. Suitable values would be \cleardoublepage
(the default if openright) and \clearpage (the default if openany). Thus, you can override
openright by defining \chapterbreak as \clearpage, provided its class has been changed to top (in
this example, parts will continue with the openright setting).

\chapter{tolists}

2.6 If defined, the usual white space written to lists (ie, List of Figures and List of Tables) is
replaced by the code in this command. If you do not want the white space when a chapter begins, define
it to empty, i.e.,
\newcommand{\chaptertolists}{}

This command is not a general tool to control spacing in lists, and is available only in titles of top
class, so it will not work with the default chapters except if you change their class (on the other hand,
\...tolists can be used in any title whose class is top).

3.7. Other Package Options

\textbf{explicit} (Package option)

2.7 With it, the title is not implicit after \langle before-code \rangle but must be given explicitly with \#1 as in, for
example:
\titleformat{\section}
{..}
{\thesection}{..}{\#1.}

(Compare it with the example in section 4.4.)

\textbf{newparttoc oldparttoc} (Package options)

Standard parts write the toc entry number in a non standard way. You may change that with
newparttoc so that titletoc or a similar package can manipulate the entry. (That works only if \part
has been redefined.)

\textbf{clearempty} (Package options)

Modifies the behaviour of \cleardoublepage so that the empty page style will be used in empty
pages.

\textbf{toctitles} (Package option)

2.6 Changes the behaviour of the optional argument in sectioning titles so that it sets only the
running heads and not the TOC entries, which will be based on the full title.

\textbf{newlineaspace} (Package option)

2.6 Replaces every occurrence of \ or \* in titles by a space in running heads and TOC entries.
This way, you do not have to repeat the title just to remove a formatting command.
Long ago (by the year 2000) I decided for some reason \part* would behave like the AMS classes and therefore there should be a contents entry for it. This is somewhat odd, indeed, but the very fact is nobody has complained until now! On the other hand, restoring the behaviour one could expect after 15 years doesn’t seem a good idea. A new page/part style is on the way, but for the moment this option restores the standard behaviour.

3.8. Extended Settings

The first argument of both \titleformat and \titlespacing has an extended syntax which allows to set different formats depending on the context. This argument can be a list of key/value pairs in the form:

\[(key)=(value), (key)=(value), (key), (key), ...\]

Currently, only pages and unnumbered versions are taken care of, besides the sectioning command name. Thus, the available keys are:

- **name.** Allowed values are \chapter, \section, etc.
- **page.** Allowed values are odd or even.
- **numberless.** A valueless key. it is not necessary unless you want to set different numbered (without this key) and unnumbered (with numberless) variants.

The basic form described above with the name of a sectioning command, say

\[\texttt{\titleformat{\section}} \ldots\]

is in fact an abbreviation for

\[\texttt{\titleformat{name=\section}} \ldots\]

Let’s suppose we’d like a layout with titles in the outer margin. We might set something like

\[\texttt{\titleformat{name=\section, page=even}[leftmargin]{\filleft\scshape}{\thesection}{.5em}{}}\]

\[\texttt{\titleformat{name=\section, page=odd}[rightmargin]{\filright\scshape}{\thesection}{.5em}{}}\]

Since the page information is written to the aux file, at least two runs are necessary to get the desired result.

The “number” version is usually fine when generating unnumbered variants since removing the label is the only change required in most cases, but if you need some special formatting, there is the numberless key which defines an alternative version for sections without numbers (namely those with level below secnumdepth, in the front and back matters and, of course, the starred version). For instance

\[\texttt{\titleformat{name=\section}{...}% The normal definition follows}\]

\[\texttt{\titleformat{name=\section, numberless}{...}% The unnumbered \% definition follows}\]

Neither \texttt{(label)} nor \texttt{(sep)} are ignored in numberless variants.

These keys are available to both \titleformat and \titlespacing. By using page in one (or both) of them, odd and even pages will be formatted differently. Actually, “even” and “odd” are well established \LaTeX terms, but misleading. In one side printing the “odd” pages refer to “even” pages as well (cf. \texttt{\oddsidemargin}).

If you intend to create different odd/even and different numbered/unnumbered versions, it is recommended defining the four variants.

If you remove the page specifier from a sectioning command you must remove the .aux file.

\footnote{The keyval package is required for making use of it.}
3.9. Creating new levels and changing the class

While the shapes and the like modify the behaviour of titles related to the surrounding text, title classes allow to change the generic behaviour of them. With the help of classes you may insert, say, a new subchapter level between chapter and section, or creating a scheme of your own. Making a consistent scheme and defining all of related stuff like counters, macros, format, spacing and, if there is a TOC, TOC format is left to the responsibility of the user. There are three classes: page is like the book \part, in a single page, top is like \chapter, which begins a page and places the title at the top, and straight is intended for titles in the middle of text.

\titleclass{\langle name \rangle}{\langle class \rangle}{\langle super-level-cmd \rangle}

If you do not use the optional argument, you just change the \langle class \rangle of \langle name \rangle. For example:

\titleclass{\part}{straight}

makes part of straight class.

When the second form is used, the level number is the following of \langle super-level-cmd \rangle. For example:

\titleclass{\subchapter}{straight}\[\chapter\]
\newcounter{subchapter}
\renewcommand{\thesubchapter}{\Alph{subchapter}}

creates a level under chapter (some additional code is shown as well, but you must add to it the corresponding \titleformat and \titlespacing settings).\footnote{If the chapter level is 0, then the subchapter one is 1; the levels below are increased by one (section is 2, subsection is 3, and so on).}

There are two sectioning commands which perform some extra actions depending of its name and ignoring the class:

- \chapter logs the string defined in \chaptertitlename and the matter is taken into account.
- \part does not encapsulates the label in the toc entry, except if you use the newparttoctoc option.

\textbf{loadonly} \hspace{1em} (Package option)

Let us suppose you want to create your sectioning commands from scratch. This package option ignores any previous definitions, if any, and hence removes the possibility of using the options described in “Quick Reference.” Then you use the titlesec tools, and define the corresponding counters and labels.

\titleclass{\langle name \rangle}{\langle start-level-num \rangle}{\langle class \rangle}

Here, the \langle name \rangle title is considered the top level, with number \langle start-level-num \rangle (typically 0 or \footnote{There is an further class named part to emulate the article \part, but you should not use it at all. Use the straight class instead. Remember some features rely in these classes and titlesec does not change by default the definition of \part and \chapter.}–1). It should be used only when creating sectioning commands from scratch with the help of loadonly, and there must be exactly one (no more, no less) declaration of this kind. After it, the rest of levels are added as explained above.

4. Additional Notes

This part describes briefly some \LaTeX commands, useful when defining sectioning titles.

4.1. Fixed Width Labels

The \makebox command allows to use fixed width label, which makes the left margin of the actual title (not the label) to lie in the same place. For instance (only the relevant code is provided):

\titleformat{\section}
{..}
{\makebox[2em]{\thesection}}{..}{..}

See your \LaTeX manual for further reference on boxing commands.
4.2. Starred Versions

Using sectioning commands in the starred version is strongly discouraged. Instead, you can use a set of
markup oriented commands which are easy to define and modify, if necessary. Thus, you can test
different layouts before choosing amongst them.

Firstly remember if you say
\setcounter{secnumdepth}{0}

sections will be not numbered but they will be included in both toc and headers.

Now, let’s suppose you want to include some sections with a special content; for example, a section
(or more) with exercises. We will use an environment named exercises whose usage is:

\section{A section}
Text of a normal section.
\begin{exercises}
\section{Exercises A}
Some exercises
\section{Exercises B}
Some exercises
\end{exercises}

The following definition suppresses numbers but neither toc lines nor headers.

\newenvironment{exercises}
{\setcounter{secnumdepth}{0}}
{\setcounter{secnumdepth}{2}}

The following one adds a toc line but headers will remain untouched:

\newenvironment{exercises}
{\setcounter{secnumdepth}{0}\
\renewcommand\sectionmark[1]{}\}
{\setcounter{secnumdepth}{2}\
\addtocontents{toc}{\protect\setcounter{tocdepth}{0}\ignorespaces}}

The following one updates the headers but there will be no toc line:

\newenvironment{exercises}
{\setcounter{secnumdepth}{0}\%
\addtocontents{toc}{\protect\setcounter{tocdepth}{0}\ignorespaces}}
{\setcounter{secnumdepth}{2}\%
\addtocontents{toc}{\protect\setcounter{tocdepth}{2}\ignorespaces}}

(I find the latter a bit odd in this particular example; the first and second options are more sensible. The
\ignorespaces is not very important, and you need not it unless there is unwanted space in the toc.)

That works with standard classes, but if you are using fancyhdr or titlesec to define headers you need
further refinement to kill the section number. In \texttt{titlesec} that’s accomplished with \texttt{tfthesection} (see
below).

As you can see, there are no \texttt{addcontentsline}, no \texttt{markboth}, no \texttt{\section*}, just logical
structure. Of course you may change it as you wish; for example if you decide these sections should be
typeset in small typeface, include \texttt{\small}, and if you realize you do not like that, remove it.

While the standard \texttt{LATEX} commands are easier and more direct for simple cases, I think the proposed
method above is far preferable in large documents.

4.3. Variants

Let’s suppose we want to mark some sections as “advanced topics” with an asterisk after the label. The
following code does the job:

\newcommand{\secmark}{}
\newenvironment{advanced}
To mark the sections write
\begin{advanced}
\section{...}
...
\end{advanced}

That marks sections but not subsections. If you like being redundant and marking the subsection level as well, you must define it accordingly.

4.4. Putting a Dot after the Section Title
Today this styling is not used, but formerly it was fairly common. The basic technique was described above, but here is a reminder:
\newcommand{\periodafter}[1]{#1.}
\titleformat{\section}{..}{\thesection}{..}{..\periodafter}

If you had to combine this dot with some command (perhaps an underlining), you can say:
\newcommand{\periodafter}[2]{#1{#2.}}
\titleformat{\section}{..}{\thesection}{..}{..\periodafter{\ul}} % \ul from soul package

However, you might prefer the package option explicit.

5. titleps and Page Styles
The titleps package provides tools for one-stage setting of page styles (headlines and footlines). A higher-level interface is used, where the mark mechanism is hidden and there is no need to deal with \leftmarks and \rightmarks – just use a command or variable registered as a “mark” as the expected value will be returned, i.e., those when the mark was emitted, either by a sectioning command or explicitly with \chaptermark, \sectionmark, etc. A simple example, whose meaning should be obvious, is:
\newpagestyle{main}{}
\sethead{\thepage}{\chaptertitle}{(\thesection\sectiontitle)} % even
(\thesection)(\sectiontitle)(\thepage) % odd
\pagestyle{main}

Other features are:
- Working top marks, compatible with floats (unlike the standard \topmark, which does not work correctly in L\TeX).
- Access to top, first and bot marks in a single headline/footline (e.g., the first and last section numbers).
- Marks for more than 2 sectioning levels.
- Simple (and not so simple) headrules and footrules.
- Headlines and footlines for pages with floats.
- Headlines and footlines for specific floats (a sort of \thispagestyle for floats).
• Multiple sets of marks (named here marksets and extra marks).

It can be used without titlesec, but you will get most of it when used together. To load it as a separate package, use the customary \usepackage{titleps}, but with titlesec you have to load it with:

\usepackage[pagestyles]{titlesec}

Please, read titleps.pdf (or typeset titleps.tex) for further information.

6. Contents: The titletoc package

This package is a companion to the titlesec package and it handles toc entries. However, it is an independent package and you can use it alone. The philosophy is similar to that of titlesec—instead of hooking the commands as defined by standard \LaTeX and classes, there are new commands which you can format the toc entries with in a generic way. This means you have to learn just two new basic command and a couple of tools, no more, and you have access to new features. Paragraph format and fonts are set with commands like \makebox, \large, \itshape, and so on, and entries are not shaped in any fashion because they are pretty free form.

The behaviour of entries defined with titletoc are different at some points to those created with the standard commands. In particular:

• Pages are never broken between entries if the first one is of an higher level than the second one as, for instance, between a section and a subsection. If both of them are of the same level, the break is allowed, and if the first is lower than the second, it is considered a good place for a page break.

• The symbols in the leaders are not centered but flushed right. That is usually more convenient.

I would like to note no attempt to handle tocs can be complete because the standard \LaTeX commands write directly some formatting commands which cannot be removed. This is particularly important in lists of figures and tables, and in the \part command.\footnote{But some of these issues are fixed by titlesec.}

6.1. A ten-minute guide to titletoc

Toc entries are treated as rectangular areas where the text and probably a filler will be written. Let’s draw such an area (of course, the lines themselves are not printed):

The space between the left page margin and the left edge of the area will be named \langle left\rangle; similarly we have \langle right\rangle. You are allowed to modify the beginning of the first line and the ending of the last line. For example by “taking up” both places with \hspace*{2pc} the area becomes:

And by “clearing” space in both places with \hspace*{-2pc} the area becomes:
If you have seen toc, the latter should be familiar to you– the label at the very beginning, the page at the very end:

3.2 This is an example showing that toc entries fits in that scheme . . . . 4

All you need is to put these elements in the right way. If you have reserved the space with \hspace*{-2pc}, simply put a box 2 pc width containing the section label or page so that this space will be retrieved; this layout is used so often that two commands are provided which does that for you:

- \contentslabel{(length)} creates the space at the beginning and prints the section number.
- \contentspage creates a space at the end of length \(\text{(right)}\) and prints the page number aligned at the right.

Now, we are about to show the three basic commands:

\dottedcontents{(section)\|\{left\}\{\{above-code\}\}\{\{label width\}\}\{\{leader width\}\}}

Here:

- \(\{section\}\) is the section name without backslash; part, chapter, section, etc. figure and table are allowed, too. (The backslash is omitted because we are dealing with the concept and not the \part, \section, etc. macros themselves. Furthermore, figure and table are environments.)
- \(\{above-code\}\) is code for the global formatting of the entry. Vertical material is allowed. At this point the value of \thecontentslabel (see below) is known which enables you to take decisions depending on its value (with the help of the ifthen package). You may use the \texttt{titlesec} \texttt{\filleft}, \texttt{\filright}, \texttt{\filcenter} and \texttt{\fillast} commands.
- \(\{left\}\) even if bracketed is currently mandatory and it sets the left margin from the left page margin.
- \(\{label width\}\) is the width of the space created for the label, as described above.
- \(\{leader width\}\) is the width of the box containing the char to be used as filler, as described below.

The definitions for section and subsection entries in the \texttt{book} class are roughly equivalent to:

\texttt{\contentsmargin{2.55em}}
\texttt{\dottedcontents{section\|\{left\}\{\{above-code\}\}\{\{label width\}\}\{\{leader width\}\}}}

Here \(\{section\}\), \(\{left\}\) and \(\{above-code\}\) like above, and

- \(\{numbered-entry-format\}\) is in horizontal mode and it will be used just before the entry title. As in \texttt{\titleformat}, the last command can take an argument with the title.
- \(\{numberless-entry-format\}\) is like the above if there is, well, no label.
- \(\{filler-page-format\}\) is self explanatory. Fillers are created with the \texttt{\titlerule} command which is shared by that package and \texttt{titlesec}. However, when used in this context its behaviour changes a little to fit the needs of toc leaders\footnote{For \TeX{}nicians, the default \texttt{xleaders} becomes \texttt{leaders}.} You might prefer a \texttt{\hspace} instead.
- And finally \(\{below-code\}\) is code following the entry for, say, vertical space.
When defining entries, use \addvspace if you want to add vertical space, and \\
\* instead of \ for
line breaks.
This command can be used in the middle of a document to change the format of toc/lot/lof entries at
any point. The new format is written to the toc file and hence two runs are necessary to see the changes.

\contentsmargin{(right)}

The value set is used in all of sections. If you are wondering why, the answer is quite simple: in most
of cases the \textit{(right)} margin will be constant. However, you are allowed to change it locally in the
\texttt{(before-code)} arguments. Note as well that the default space in standard classes does not leave room to
display boldfaced page number above 100 and therefore you might want to set a larger margin with this
command.
The \texttt{book} class formats section entries similarly (but not equally) to:

\titlecontents{section}
  [3.8em] % ie, 1.5em \texttt{(chapter)} + 2.3em
  {} %
  {\contentslabel{2.3em}} %
  {\hspace*{-2.3em}}
  {\titlerule*[1pc]{.}\contentspage}

Compare this definition with that given above and you will understand how \texttt{dottedcontents} is
defined.
Although standard classes use font dependent units (mainly em), it is recommended using absolute
ones (pc, pt, etc.) to ensure they entries are aligned correctly.

6.2. And more
Strict typographical rules state full text lines shouldn’t surpass the last dot of the leaders; ideally they
should be aligned. Surprisingly enough, \LaTeX lacks of a tool for doing that automatically—when you fill
a box with leading dots, they can be centered in the box with the \texttt{\cleaders} primitive, “justified” with
\texttt{\xleaders} or aligned with the outermost enclosing box with \texttt{\leaders}, but there is no way to align
them with the “current” margin.
So, the only way to get a fine layout is by hand. To do so, you can use the an optional argument in the
\contentsmargin command whose syntax in full is the following:

\contentsmargin\{(correction)\}{(right)}

The \texttt{(correction)} length is added to the \texttt{(right)} one in all of lines except the last one, where the leaders
are placed. For instance, if the text lines are 6 pt longer than the last dot, you should rewrite the
\contentsmargin command to add a \texttt{(correction)} of 6 pt.\footnote{Usefully, many dvi previewers allow to get the coordinates of the pointed location.} Unlike the standard \LaTeX tools, the
\titlerule* command has been designed so that the \texttt{(correction)} will have the minimum value
possible.

\thecontentslabel \thecontentspage

Contains the text with the label and the page with no additional formatting, except written by the
class.

\contentslabel\{format\}\{space\}
\contentspage\{format\}

As described above, but with different \texttt{(format)}s. The defaults are just \texttt{\thecontentslabel} and
\texttt{\thecontentspage}, respectively.
\texttt{\textbackslash contentspush\{\texttt{text}\}}

Prints the \texttt{text} and increases \texttt{\langle left\rangle} by the width of \texttt{text}. It is similar to the hang shape of titlesec.

\texttt{\textbackslash titlecontents*\{\langle section\rangle\}[\langle left\rangle][\langle above-code\rangle]
{\langle numbered-entry-format\rangle}[\langle numberless-entry-format\rangle]
{\langle filler-page-format\rangle}[\langle separator\rangle]
or \ldots{\langle filler-page-format\rangle}[\langle separator\rangle][\langle end\rangle]
or \ldots{\langle filler-page-format\rangle}[\langle begin\rangle][\langle separator\rangle][\langle end\rangle]}

This starred version groups the entries in a single paragraph. The \texttt{\langle separator\rangle} argument is the separator between entries, and there is a further optional argument with an ending punctuation. For example, this document sets:

\texttt{\textbackslash titlecontents*\{subsection\}[1.5em]
{\small}
{\thecontentslabel.}
{\}
{\}, \thecontentspage}
[\ldots][.]

whose result is showed in the contents at the very beginning of this document. Note the paragraph format must be written in the \texttt{\langle above-code\rangle} argument.

Let us explain how the optional arguments works. First note the number of them determines their meaning—since there should be a separator between entries this one is always present; on the other hand, \texttt{\langle begin\rangle} is rarely used and hence it has the lowest “preference.” The simplest case is when the titles are of the same level; in this case the \texttt{\langle separator\rangle} and the \texttt{\langle end\rangle} parameters (which default to empty) are inserted between consecutive entries and at the end of the block, respectively. \texttt{\langle before-code\rangle} is executed just once at the very beginning of the block and its declarations are local to the whole set of entries.

Now suppose we want to group entries of two levels; in this case a nesting principle applies. To fix ideas, we will use section and subsection. When a subsection entry begins after a section one, \texttt{\langle before-code\rangle} is executed and \texttt{\langle begin\rangle} of subsection is inserted, which should contain text format only. Then subsections are added inserting separators as explained above. When a section arrives, the ending punctuation of subsection and the separator of section is added (except if the block is finished by a subsection, where the ending of section is added instead). We said “after a section” because a subsection never begins a block.\footnote{In rare cases that could be necessary, yet.} The subsection entries are nested inside the section ones, and declarations are again local.

An example will illustrate that.

\texttt{\textbackslash titlecontents*\{section\}[Opt]
{\small \itshape}{}
{}
{}
{}
{}
\texttt{\textbackslash titlecontents*\{subsection\}[Opt]
{\upshape}{}
{\}, \thecontentspage}
[\ldots][.]

produces something similar to:

\textit{The first section \• The second one \• The third one} (A subsection in it, 1. Another, 2) \• \textit{A fourth section} (A subsection in it, 1. Another, 2).

\texttt{\textbackslash contentsuse\{\langle name\rangle\}[\langle ext\rangle]}

Makes \texttt{titletoc} aware of the existence of a contents file with \texttt{\langle ext\rangle} extension. Mainly, it makes sure the command \texttt{\textbackslash contentsfinish} is added at the end of the corresponding contents (and which must be added at the end of tocs made by hand). The package performs
These package options set how the labels are aligned in `\contentslabel`. Default is `rightlabels`. With `leftlabels` the default (format) for `\contentslabel` becomes `\thecontentslabel\enspace`.

With this package option, a dot is added after the label in `\contentslabel`.

**6.3. Partial TOC’s**

`\startcontents[⟨name⟩]`

At the point where this command is used, a partial toc begins (note the document doesn’t require a `\tableofcontents` for partial tocs to work). The `⟨name⟩` argument allows different sets of tocs and it defaults to `default`. These sets may be intermingled, but usually will be nested. For example, you may want two kinds of partial tocs: by part and by chapter (besides the full toc, of course). When a part begins, write `\startcontents[parts]`, and when a chapter `\startcontents[chapters]`. This way a new toc is started at each part and chapter.

`\stopcontents[⟨name⟩]`

`\resumecontents[⟨name⟩]`

Stops the partial toc of `⟨name⟩` kind, which may be resumed. Since partial contents are stopped by `\startcontents` if necessary, those macros will not be used very often.

`\printcontents[⟨name⟩][⟨prefix⟩][⟨start-level⟩][⟨toc-code⟩]`

Print the current partial toc of `⟨name⟩` kind. The format of the main toc entries are used, except if there is a `⟨prefix⟩`. In such a case, the format of `⟨prefix⟩⟨level⟩` is used, provided it is defined. For example, if prefix is `1` and the format of `\lsection` is defined, then this definition will be used; otherwise, the format is that of `section`. The `⟨start-level⟩` parameter sets the top level of the tocs—for a part toc it would be `0` (chapter), for a chapter toc `1` (section), and so on. Finally, `⟨toc-code⟩` is local code for the current toc; it may be used to change the `tocdepth` value or `\contentsmargin`, for instance.

A simple usage might look like (provided you are using `titlesec` as well):

```latex
\titleformat{\chapter}[display]
{\\vspace*{4pc}\startcontents}
{\printcontents{l}{1}{\setcounter{tocdepth}{2}}}
```

The included entries are those in levels 1 to 2 inclusive (i.e., 1 and 2).

**6.4. Partial lists**

You may want to create partial LOFs and LOTs. The syntax is similar to that of partial TOCs and what was said for them can be applied here. The commands are:

`\tokenlist[⟨name⟩]`

`\stoplist[⟨name⟩]`

`\resumelist[⟨name⟩]`

Print the current partial list of `⟨name⟩` kind. The format of the main list entries are used, except if there is a `⟨prefix⟩`. In such a case, the format of `⟨prefix⟩⟨level⟩` is used, provided it is defined. For example, if prefix is `1` and the format of `\lsection` is defined, then this definition will be used; otherwise, the format is that of `section`. The `⟨start-level⟩` parameter sets the top level of the tocs—for a part toc it would be `0` (chapter), for a chapter toc `1` (section), and so on. Finally, `⟨toc-code⟩` is local code for the current toc; it may be used to change the `tocdepth` value or `\contentsmargin`, for instance.

A simple usage might look like (provided you are using `titlesec` as well):

```latex
\titleformat{\chapter}[display]
{\\vspace*{4pc}\tokenlist}
{\stoplist}
```

The included entries are those in levels 1 to 2 inclusive (i.e., 1 and 2).
\startlist\[\] {\langle list\rangle} \stoplist\[\] {\langle list\rangle} 
\resumelist\[\] {\langle list\rangle} 
\printlist\[\] {\langle list\rangle} {\langle prefix\rangle} {\langle toc-code\rangle}

Here \langle list\rangle is either \texttt{lof} or \texttt{lot}. Note as well \texttt{printlist} does not have the \texttt{(start-level)} argument, because figures and tables have not levels. Currently, only those two float lists are supported, but in a future release support for more kinds of float lists will be added. Unfortunately, many classes write some formatting commands to these lists (more precisely, \texttt{\addvspace} in chapters); I’m still not sure how to remove these commands for more kinds of float lists without removing as well others which can be wanted, but for the time being a quick trick to remove these spaces is to \texttt{redefine \addvspace} in the \langle toc-code\rangle with \texttt{\renewcommand\addvspace[1]{}}.

6.5. Examples
\texttt{\titlecontents{chapter}} [0pt] {\addvspace{1pc}\% \itshape} {\contentsmargin{0pt}\% \bfseries \makebox[0pt][r]{\huge \thecontentslabel \enspace} \large} {\contentsmargin{0pt}\large} {\quad \thepage} \[\addvspace{.5pc}\%

The chapter number is out at the edge of the page margin, in a font larger than the font of the title. If the chapter lacks of number (because, say, it is the preface or the bibliography) it is not boldfaced. The page number follows the title without fillers, but after an em-space.

\texttt{\titlecontents{chapter}} [3pc] {\addvspace{1.5pc}\% \filcenter} \[\texttt{CHAPTER \thecontentslabel\*\[.2pc]\% \huge} \{\huge \} \% That is, without page number \[\addvspace{.5pc}\]

The chapter title is centered with the chapter label on top of it. There is no page number.

6.6. Inserting a figure in the contents
The \texttt{\addtocontents} command is still available and you may use it to perform special operation, like inserting a figure just before or after of an entry. Sadly, fragile arguments are not allowed and writing complex code could be a mess. The trick is to define a command to perform the required operations which in turn is written with \texttt{\protect}.

Let’s suppose we want to insert a figure before an entry.

\newcommand{\figureintoc}[1]{
\begin{figure}
\includegraphics{#1}\%
\end{figure}}

makes the dirty work.

In the place where a figure is inserted write:

\texttt{\addtocontents{\protect\figureintoc{myfig}}}
6.7. Marking entries with asterisks

Let’s now resume a problem explained in relation with \texttt{titlesec}: marking sections with asterisks to denote an “advanced topic” unless the star should be printed in the toc as well. Here is the code:

\begin{verbatim}
\newcommand{\secmark}{}
\newcommand{\marktotoc}[1]{\renewcommand{\secmark}{#1}}
\newenvironment{advanced}{\renewcommand{\secmark}{*}%
  \addtocontents{toc}{\protect\marktotoc{*}}}
\titleformat{\section}{..}{\thesection\secmark}{..}{..}
\titlecontents{section}[..]{..}
{\contentslabel[thecontentslabel]{1.5pc}}{..}{..}
\end{verbatim}

7. The titlesec philosophy

Once you have read the documentation it should be clear this is not a package for the casual user who likes the standard layout and wants to make simple changes. This is a tool for the serious typographer who has a clear idea of what layout wants and do not have the skill to get it. No attempt is made to improve your taste in section formatting.

8. Appendix

The following examples will be illustrative. In this part, the \texttt{\sloppy} is 0 pt.

9 This is an example of the section command defined below and, what’s more, this is an example of the section command defined below

\begin{verbatim}
\titleformat{\section}{block}{\normalfont\bfseries\filcenter}{1em}{\fbox{\itshape\thesection}}
\end{verbatim}

\begin{verbatim}
\titleformat{\section}{frame}{\normalfont}{8pt}{\Large\bfseries\filcenter}
\end{verbatim}

11. A Ruled Title

\begin{verbatim}
\titleformat{\section}{titlerule\vspace{.8ex}\
ormalfont\itshape}{\thesection.}{.5em}{}
\end{verbatim}
Another Ruled Title
\titleformat{\section}[block]{\normalfont\sffamily}{\thesection}{.5em}{\titlerule\[.8ex]\bfseries}
\titleformat{\section}[block]{\filcenter\large\addtolength{\titlewidth}{2pc}\%\titlline*[c]{\titlerrule*[.6pc]{\tiny\textbullet}}\%\addvspace{6pt}\%\normalfont\sffamily}{\thesection}{1em}{}
\titlespacing{\section}{5pc}{*2}{*2}\%\titlespacing{\section}{3pc}{*3}{*2}\%\titlespacing{\section}{\parindent}{*2}{\wordsep}

\section{15}
This is an example of the section command defined below and, what’s more, this is an example of the section command defined below. Let us repeat it. This is an example of the section command defined below and, what’s more, this is an example of the section command defined below

\section{16. A Simple Example of the “wrap” Section Shape}
Which is followed by some text to show the result. Which is followed by some text to show the result. Which is followed by some text to show the result. Which is followed by some text to show the result. Which is followed by some text to show the result.
17. And another  Note how the text wraps the title and the space reserved to it is readjusted automatically. And it is followed by some text to show the result. Which is followed by some text to show the result.

\titleformat{\section}[wrap]{\normalfont\fontseries{b}\selectfont\filright}{\thesection.}{.5em}{\titlerule*[.6em]{\bfseries.}}
\titlespacing{\section}{12pc}{1.5ex plus .1ex minus .2ex}{1pc}

§ 18. Old-fashioned runin title.—Of course, you would prefer just a dot after the title. In this case the optional argument should be [. ] and the space after a sensible value (1em, for example).

\titleformat{\section}[runin]{\normalfont\bfseries}{\S\ \thesection.}{.5em}{}[.---]
\titlespacing{\section}{\parindent}{1.5ex plus .1ex minus .2ex}{0pt}

Example of margin section Which is followed by some text to show the result. But do not stop reading, because the following example illustrates how to take advantage of other packages. The last command in the last argument can take an argument, which is the title with no additional command inside it. We just give the code, but you may try it by yourself. Thus, with the soul package you may say

\newcommand{\secformat}[1]{\MakeLowercase{\so{#1}}}
% \so spaces out letters
\titleformat{\section}[block]{\normalfont\scshape\filcenter}{\thesection}{1em}{\secformat}

The margin title above was defined:

\titleformat{\section}[leftmargin]{\normalfont \titlerule*[.6em]{\bfseries.}\vspace{6pt}\sffamily\bfseries\filleft}{\thesection.}{.5em}{\titlerule*[.6em]{\bfseries.}}
\titlespacing{\section}{4pc}{1.5ex plus .1ex minus .2ex}{1pc}

The following examples are intended for chapters. However, this document lacks of \chapter and are showed using \sections with slight changes.

---

CHAPTER 19

The Title

\titleformat{\chapter}[display]
CHAPTER XX

The Title

\renewcommand{\thechapter}{\Roman{chapter}}
\titleformat{\chapter}[display]{\bfseries\Large}{\MakeUppercase{\chaptertitlename} \Huge\thechapter}{4ex}{\titlerule}
\titlespacing{\section}{-6pc}{3.5ex plus .1ex minus .2ex}{1.5ex minus .1ex}
\titleformat{\paragraph}[leftmargin]{\sffamily\slshape}{\filright}{}{}
\titlespacing{\paragraph}{5pc}{1.5ex minus .1 ex}{1pc}
\widenhead{6pc}{0pc}

9.1. A full example

Now an example of a complete title scheme follows.

\documentclass[twoside]{report}
\usepackage[sf,sl,outermarks]{titlesec}

% \chapter, \subsection...: no additional code

\titleformat{\section}[\sffamily\slshape]{\filcenter}{\thesection}{1em}{}
\titleformat{\paragraph}[\sffamily\slshape]{\filright}{}{}{}
\titlespacing{\paragraph}{5pc}{1.5ex minus .1 ex}{1pc}
% 5+1=6, ie, the negative left margin in section
\widenhead{6pc}{0pc}
9.2. Standard Classes

Now follows, for your records, how sectioning commands of standard classes could be defined.

\titleformat{\chapter}[display]
{\normalfont\huge\bfseries}{\chaptertitlename \thechapter}{20pt}{\Huge}
\titleformat{\section}
{\normalfont\Large\bfseries}{\thesection}{1em}{\normalfont\Large\bfseries}
\titleformat{\subsection}
{\normalfont\large\bfseries}{\thesubsection}{1em}{\normalfont\large\bfseries}
\titleformat{\subsubsection}
{\normalfont\normalsize\bfseries}{\thesubsubsection}{1em}{\normalfont\normalsize\bfseries}
\titleformat{\paragraph}
{\normalfont\normalsize\bfseries}{\theparagraph}{1em}{\normalfont\normalsize\bfseries}
\titleformat{\subparagraph}
{\normalfont\normalsize\bfseries}{\thesubparagraph}{1em}{\normalfont\normalsize\bfseries}
\titlespacing*{\chapter}{0pt}{50pt}{40pt}
\titlespacing*{\section}{0pt}{3.5ex plus 1ex minus .2ex}{2.3ex plus .2ex}
\titlespacing*{\subsection}{0pt}{3.25ex plus 1ex minus .2ex}{1.5ex plus .2ex}
\titlespacing*{\subsubsection}{0pt}{3.25ex plus 1ex minus .2ex}{1.5ex plus .2ex}
\titlespacing*{\paragraph}{0pt}{3.25ex plus 1ex minus .2ex}{1em}
\titlespacing*{\subparagraph}{\parindent}{3.25ex plus 1ex minus .2ex}{1em}

9.3. Chapter Example

A final example shows how to take advantage of the picture environment for fancy sectioning formats. Even with the simple tools provided by standard \LaTeX you may create impressive titles but you may devise more elaborated ones with, for instance, pspicture (PSTricks package) or by including graphics created with the help of external programs.

\usepackage[dvips]{color}
\usepackage[rigidchapters,explicit]{titlesec}
\DeclareFixedFont{\chapterfont}{T1}{phv}{bx}{n}{11cm}
\titlespacing{\chapter}{0pt}{0pt}{210pt}
% Most of titles have some depth. The total space is
% a bit larger than the picture box.
\titleformat{\chapter}[block]
{\begin{picture}(330,200)}
{\put(450,80){%}
 \makebox(0,0)[rb]{{\chapterfont\textcolor[named]{SkyBlue}{\thechapter}}}\}
{\put(0,230){%}
 \makebox(0,0)[lb]{{\Huge\sffamily\underline{Chapter \thechapter}}}}\}
{0pt}
{\put(0,190){%}
 \parbox[t]{300pt}{%}
 \Huge\sffamily\filright#1}}\}
{\end{picture}}

(The exact values to be used depend on the text area, class, unitlength, paper size, etc.)
