The *somedefs* toolkit package

Overview

This is an example ‘programmers toolkit’ package, for use by package writers. It allows package writers to provide options which switch definitions on and off. For example, a package *fred* might define a large number of commands, including \foo and \baz, so:

\begin{verbatim}
\usepackage{fred}
\end{verbatim}

would use a lot of memory, even if \foo and \baz were the only commands needed. However, if the author of *fred* used the *somedefs* package, then the user would be able to say:

\begin{verbatim}
\usepackage[only,foo,baz]{fred}
\end{verbatim}

and only the commands \foo and \baz would be defined.

To use the *somedefs* package in your own packages or classes, you say:

\begin{verbatim}
\RequirePackage{somedefs}
\end{verbatim}

You can then use four new commands:

- \texttt{\UseAllDefinitions} which says that all the commands in the file should be defined.
- \texttt{\UseSomeDefinitions} which says that only the commands specified by \texttt{\UseDefinition} should be defined.
- \texttt{\UseDefinition{⟨name⟩}} which says that the command \texttt{\name} should be defined.
- \texttt{\ProvidesDefinition{⟨definition⟩}} which provides one definition, of the form \texttt{\definingcommand{\command}...}
For example, the package \texttt{fred} could say:

\begin{verbatim}
\RequirePackage{somedefs}
\UseAllDefinitions
\DeclareOption{only}{\UseSomeDefinitions}
\DeclareOption*{\UseDefinition{\CurrentOption}}
\ProcessOptions
\ProvidesDefinition{\newcommand{\foo}{...}}
\ProvidesDefinition{\newcommand{\baz}{...}}
\end{verbatim}

One of the commands \texttt{\UseAllDefinitions} or \texttt{\UseSomeDefinitions} should always be used. You may have some commands which need other commands, in which case you have to declare the options by hand. For example, if the command \texttt{\bar} needs the command \texttt{\foo}, you could say:

\begin{verbatim}
\DeclareOption{bar}{\UseDefinition{bar}\UseDefinition{foo}}
\end{verbatim}

For a longer example of the use of the \texttt{somedefs} package, look at the \texttt{rawfonts} package.

### Implementation

The driver for the documentation you're now reading.

\begin{verbatim}
\def\UseSomeDefinitions{\let\ProvidesDefinition\@providesdefinition}
\def\UseAllDefinitions{\let\ProvidesDefinition\@firstofone}
\def\UseDefinition#1{\expandafter\let\csname#1\endcsname\@unprovided@definition}
\def\ProvidesDefinition#1{\PackageError{somedefs}{No \noexpand\UseSomeDefinitions or \string\UseAllDefinitions}}
\end{verbatim}

The package works by having \texttt{\UseDefinition{⟨name⟩}} define \texttt{⟨name⟩} to be \texttt{\@unprovided@definition}. If \texttt{\UseSomeDefinitions} has been called, then \texttt{\ProvidesDefinition} looks to see if \texttt{⟨name⟩} is \texttt{\@unprovided@definition}. If \texttt{\UseAllDefinitions} has been called, then \texttt{\ProvidesDefinition} does nothing. If neither has been called, then \texttt{\ProvidesDefinition} produces an error message.
The package which used the 'somedefs' package has an error.

\def\@providesdefinition#1{\@provides@definition#1\relax
\@provides@definition}
\def\@provides@definition#1#2#3\@provides@definition{%
\ifx#2\@unprovided@definition
#1#2#3%
\fi
\@onlypreamble\UseSomeDefinitions
\@onlypreamble\UseAllDefinitions
\@onlypreamble\UseDefinition
\@onlypreamble\ProvidesDefinition
\@onlypreamble\@providesdefinition
\@onlypreamble\@provides@definition

That's it!
